Build Service

Requirements Document

Author: Steve Jones
Date: 4/18/2014

The purpose of this project is to design and implement a system for regular (nightly or other experiment-level) software builds by Frontier experiments and related software providers at Fermilab. Presently, many software packages are built (on a nightly basis) on interactive nodes. While this is easy to set up, the builds can take a long time—up to many hours. Limitations include I/O bandwidth, e.g., from use of network-attached storage, such as NFS or AFS; and a limited number of processors/cores, which limits parallelism in the build process. Individual users building code for their own analyses face similar problems, long compile and link times, probably for the same reasons.

I. Executive Summary

The architecture from this project should enable continuous integration (software building, validation, testing) for multiple experiments and projects. The system should be reasonably easy for experiment developers and software librarians to use; affordable within expected budget constraints; and maintainable without undue expense or administration effort. Support for remote build machines is considered in scope for this project.

II. Requirements Summary

Provide a high level list of the requirements for this project.

No.	Requirement	Category	Source	Priority
1.	Hardware: Hardw		Glenn Cooper	High
1.a	Memory requirements are modest, 2 GB/core (as an average)are sufficient	Hardware	Glenn Cooper	High
1.b	Begin with a few 16-core systems	Hardware	Glenn Cooper	High
1.c	Need at least one running SLF5 Hardware Glenn Cooper and one running SLF6		High	
1.d	Can add other platforms (Mac; Ubuntu, SUSE; ARM;) later Glenn Cooper		High	
1.e	Few TB local disk Hardware Glenn Coope		Glenn Cooper	High
2.	A survey of existing solutions must be performed and a report that presents the arguments for a choice must be drafted. Free Software or Open Source solutions must be considered first and proprietary systems only considered if no FOSS solutions are suitable. The Framework should support:	Operational	Glenn Cooper/Brett Viren LBNE/LArSoft	High
2.a	Continuous integration is desired.	Operational	Glenn Cooper	High
2.b	The system must retain an association between a job run and a particular state (commit) of the repository holding the main software being tested.	Operational	Brett Viren from LBNE/LArSoft	High
2.c	Incremental and green-field	Operational	Brett Viren	High

		Ī	<u></u>	T
	building of the entire		from

	re-run of any job, even if it		from	
	was previously successful.		LBNE/LArSoft	
2.h.4	System should allow user to	Operational	3/21/Meeting	Low
	view errors in jobs run and			
	provide links to access the			
	provide links to access the			

	file system of jobs			
3.	Reporting:	Operational	Glenn Cooper	High
3.a	Provide current status of each job	Operational	Glenn Cooper	High
3.b	Show the success/failure of completed jobs	Operational	Glenn Cooper	High
3.c	Show resources used	Operational	Glenn Cooper	High
3.d	Report on job results be they success and failure must be stored and made available for browsing via the web.	Operational	Brett Viren from LBNE/LArSoft	High
3.e	Provide report that should indicate what triggered the job. (possibly interfacing with Redmine)	Operational	Brett Viren from LBNE/LArSoft	High
3.f	Historical success/failure rates of builds	Operational	3/21/Meeting	High
3.g	Days since last successful/unsuccessful build for each slave	Operational	3/21/Meeting	High
4.	Be robust enough to be able to support the number of potential participants (experiments, projects)	Operational	Glenn Cooper	High
4.a	IF experiments: 10 (g-2, LBNE, MicroBooNE, MINERvA, MINOS, Mu2E, NOvA, SciBooNE, SeaQuest)	Operational	Glenn Cooper	High
4.b	CF experiments: 3 (DarkSide, DES, LSST)	Operational	Glenn Cooper	High
4.c	Software projects: 3 (LArSoft, art, GENIE)	Operational	Glenn Cooper	High
4.d	Expandable for growth for 10 additional future participants	Operational	Steve Jones	Medium
5.	Builds must support working with offsite hardware (e.g., BNL).	Operational	Brett Viren from	High

				LBNE/LArSoft	
6.	Termir	nology:	Operational	3/14 and	High
		Build Platform(s): includes OS version; compiler version; optionally other details Build Service: monitor,		3/21 Meeting	
		coordinate; support build for remote sites; works with meta data for each slave; basically integration service			
	3.	continuous integration or build automation software			
		Build Master = Service Machine Build Slave = Platform			
	5.	Machine			
7.	Securi	ty and Access Requirements	Operational	3/14 Meeting	High
7.a		System must provide user levels to create new jobs, to run jobs and to access reports on jobs	Operational	3/21/Meeting	High
7.b	Each machine must comply with the security policies active at its hosting site. Inter-node communication must be consistent with the security policies at all relevant sites.				
8.	Docun	nentation Requirements	Operational	3/14 Meeting	High
8.1	Prior to initial deployment, documentation for expert users in the experiments must be provided (eg. Wiki Users Guide)		Operational	3/21/Meeting	High
9.	Redmine Integration		Operational	3/14 Meeting	Low (but provided by all leading candidates)

9.1	Build failures trigger bug report	Operational	3/21/Meeting	Low
9.2	Build reports stored on both Master server and Redmine	Operational	3/21/Meeting	Low
9.3	Redmine provides status of Master	Operational	3/21/Meeting	Low
9.4	Build project history stored on Redmine	Operational	3/21/Meeting	Low
10.	Build process needs to be integrated with the Computing Sector's Service Strategy/Service Design	Operational	Steve Jones/ Mike Kaiser	High

III. Assumptions, Risks, Dependencies

- 1. There are several options for frameworks that need to be evaluated. Options include, in very rough order of interest expressed:
 - BuildBot (Python based; used by MINERvA)
 - Jenkins (Java based; used by CMS, LHCb)
 - Trac/Bitten/Nose (Python based; used by Daya Bay)
 - NICOS (shell scripts, Python; used by ATLAS, developed in house)
 - · Condor or other batch system
 - Cron entries
 - Many others—this is by no means a comprehensive list.
- 2. Resources to conduct the project are available within currently assigned staff.
- 3. Project cost is level of effort only except for Project Management costs.
- 4. Hardware can be reallocated from existing sources or will be identified and procured within existing budgets.

IV. Out of Scope

- 1. The initial scope does not include a facility for individual experiment members to build/test their own analysis code. That could be considered in a later project or a new phase of this project.
- 2. The system does not perform software delivery functions; this is the responsibility of individual jobs.

V. Performance and Key Success Metrics

- Function
 - Build service architecture defined
 - Overall design of the build service completed:
 - Hardware elements identified
 - Mechanisms to schedule builds: software package, batch system, etc. defined

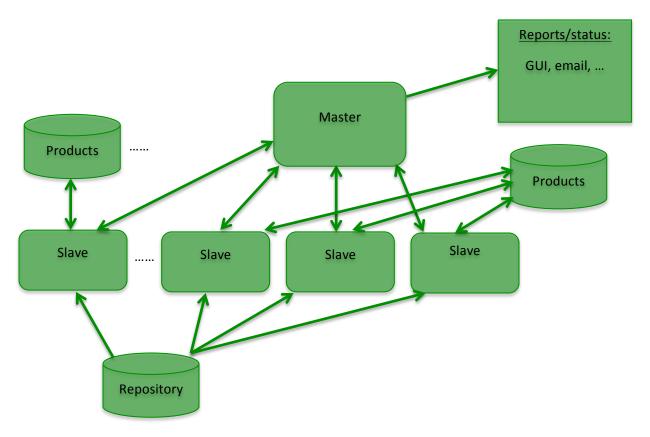

- o Hardware procurement and installation (if new hardware is required) complete
- Build system configuration and testing completed
- o Framework for supervision and administration of the build service deployed
- Transaction Throughput sufficient for users
- Batch Throughput sufficient for users
- Users
 - IF experiments: 10 (, g-2, LBNE, MicroBooNE, MINERvA, MINOS, Mu2E, NOvA, SciBooNE, SeaQuest), CF experiments: 3 (DarkSide, DES, LSST) and Software projects: 2 (LArSoft, art) and potential future users are able to simultaneous bluild each night

VI. Use Cases

- 1. Nightly (or other periodic) code build
 - a. Actors: an experiment, a project, or a major component of one
 - b. Schedule is set on master
 - c. May also include unit tests, validation modules; or these can be separate
 - d. Collects changes made over specified period
- 2. Continuous integration
 - a. Jobs launched by [particular classes of] code check-ins; time intervals; or other triggers
 - b. Typically runs unit tests along with each build
- 3. Build for additional platforms
 - a. "Platform" may include OS version; compiler version; hardware type; etc.
 - b. Master can send jobs to any platform; build requires only a slave with the desired characteristics
- 4. Manual (aperiodic) code build
 - a. Actors: an experiment, a project, or a major component of one
 - b. Input manually on master
 - c. May also include unit tests, validation modules; or these can be separate

VII. Architecture

The figure below shows a high-level view of the build system to be implemented:

Build automation software running on the master schedules build, test, and validation jobs. To start a scheduled job, the master selects a slave and sends scripts or other information to the slave. On the slave, the job pulls source code and other data, if any, from one or more repositories; for an incremental build or validation, the slave may also pull from or push to one or more output "products" areas. The master keeps track of the status of each job on each slave, visible typically via a web interface, email notifications, and other mechanisms. When a job completes, it sends status and other metadata to the master, and copies its products—built binaries, test results, or other information—to specified destinations.

VIII. Detailed Technical and System Requirements

- 1. Build automation software (or continuous integration software)
 - a. Runs on master
 - b. Must be maintainable and supportable with minimum level of effort
 - c. Process for users to schedule/submit jobs must be simple
 - d. Client software must be supported on all required platforms (see user requirements)
 - e. Needs a way to trigger a rebuild, i.e., repeat a build
 - f. Must track and make viewable:
 - i. Job status

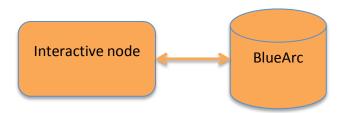

- ii. Success/failure of each job
- iii. Resources used by each job
- iv. Historical records of ii and iii
- g. Must support submissions by multiple users
- h. Must be scalable to allow for growth in number of experiments/projects and in number of builds by each
- i. Must be able to send jobs to slaves both at Fermilab and at other locations
- j. Open source preferred

2. Hardware

- a. Master
 - i. Needs modest CPU, RAM, local storage
 - ii. Suitable for a VM
 - iii. Will run Scientific Linux
- b. Slaves
 - i. For frequent builds, need multiple cores, at least modest local storage
 - ii. At least one slave of each required hardware type; but some can be remote
 - iii. For infrequent builds, could use smaller (physical or virtual) systems
 - iv. Can be at other (non-Fermilab) sites
- c. Additional platforms for logins and interactive builds?

IX. Detailed Business Process Flow Diagrams

 Most common current method: Log in, build/test/validate on same node. Source code read from network-attached storage; results written to network-attached storage.

 Central build system design: Jobs sent from master to slaves with local storage; see Architecture section above.

X. Reports

- o Current status of each job
- Success/failure of completed jöbs
- o Historical success/failure of jobs
- o Resources used
- o Days since last successful/unsuccessful build
- o What triggered job

XI. Stakeholders

Group	Name	Role
SCD	Ruth Pordes, Stu Fuess Sponsors	
FEF	Stu Fuess	Implementation Owner
NOvA	Andrew John Norman	Users
Minerva	Gabriel Perdue	Users
LBNE	Eileen F. Berman, Qizhong Li, Brett Viren	Users
Microboone	Stephen A. Wolbers	Users
Muon g-2	Adam L. Lyon	Users
Darkside 50	Kenneth Richard Herner	Users
Minos	Arthur E. Kreymer	Users
SciBoone		Users
SeaQuest		Users
DES		Users
LSST		Users
